PROVISIONAL INFORMATION ON SELECTED NOTIFIABLE DISEASES IN THE UNITED STATES AND ON DEATHS IN SELECTED CITIES FOR WEEK ENDED DECEMBER 12, 1964

SPECIAL REPORT - Meningococcal Meningitis

## Rabies

# EPIDEMIOLOGIC NOTES

Only one case of human rabies has been reported thus far this year (see MMWR, Vol. 13, No. 38), as in 1963. The figure opposite shows the incidence of human rabies since 1938. The decline in cases has paralleled the decline in animal rabies cases which began in 1946 and continued until 1960.

Since 1960, there has been a slight upward trend in reported cases of animal rabies. This trend, due to an increased incidence of rabies in wild animals, has accelerated during 1964. There are 4,353 cases of animal rabies reported thus far this year as compared to 3,608 cases for the similar period of 1963; a 21 percent increase. The increased number of animal rabies cases is largely accounted for by an increased incidence of skunk rabies in the midwest and fox rabies in Virginia and Tennessee.

SPECIAL REPORT - Meningococcal Meningitis

#### MENINGOCOCCAL MENINGITIS

In the United States, the national incidence of meningococcal meningitis has shown but a slight increase (figure 1). Through the 50th week of this year, 2,615 cases were reported compared to 2,253 cases for the comparable period last year.

During the past 18 months, meningococcal infections have assumed a special significance because of outbreaks among military recruits, caused primarily by Group B strains which are resistant to the usual prophylactic and therapeutic doses of sulfonamide drugs. The resulting lack of an effective chemoprophylactic agent is of concern to both military and civilian health officers. Since 1963. when significant numbers of sulfonamide-resistant meningococcal infections were first recognized at the San Diego Naval Training Center, the problem has been under intensive study. During recent months, a similar problem has been recognized among military recruits stationed at Fort Ord, California. On the advice of the Surgeon General of the Army, the assignment of new basic trainees to Fort Ord as of October 11, 1964 was discontinued and all basic training at that facility during the month of December was stopped.

The occurrence of meningococcal infections in California and at Fort Ord during the past 5 years is summarized in Table 1. A progressive increase in the number of cases per year is evident both in California and at Fort Ord. The increasing number of cases at Fort Ord, however, has not been paralleled by an increasing number of cases in Monterey County. Most striking is the fact that in 1964 through mid-November, Monterey County reported only one case of meningococcal meningitis exclusive of cases from Fort Ord.

1964*	473	1	84**	- 11	7	1	91	12			

<sup>\*</sup> Through Navember 14.

The month of onset of the 101 meningococcal infections and the deaths among Fort Ord personnel and their dependents in 1964 are shown in Figure 2. Not included in this total are 3 additional cases of meningitis, including one death, that occurred away from Fort Ord in October, one in a dependent, and two in non-dependent civilians. All had contact with a Fort Ord trainee several days prior to the onset of disease.

It is apparent that a substantial reduction in the number of cases per month occurred in September and

<sup>\*</sup>CASES REPORTED THROUGH NOVEMBER 17.

<sup>\*\*</sup> Six additional cases of meningitis, 3 of which ware fotal, accurred among trainacs within 2 weeks following completion of basic training or Fort Ord. Four other localized monity agracaces infactions occurred among trainess (urathritis, conjunctivitis, and mostilary sinusitis).

October following the August peak. This coincided with the introduction of a number of prophylactic measures to be described.

The disease among military personnel has been one of recruits, occurring almost solely during the 8 weeks of basic combat training, or shortly thereafter. (Figure 3) During the past several months there has been a tendency for the disease to occur during the last 4 weeks of basic combat training or within one week after its completion, rather than during the first 4 weeks, as was formerly the case. An explanation for this change has not been apparent.

Rates of nasopharyngeal carriage have been monitored regularly. Recent results indicate that the meningococcal carrier rate among inductees arriving at Fort Ord ranges from 15 ro 25 percent. By the seventh week of training, this rate may reach as high as 80 percent. The cumulative carrier rate by the end of basic combat training approaches 100 percent. Most of the strains from both cases and carriers have been Group B; Group C strains have accounted for approximately 10 percent of the isolates.

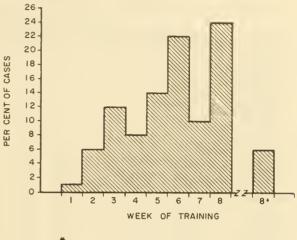

The outstanding characteristic of the meningococci recently prevalent is sulfonamide resistance. With recognition at Fort Ord in 1963 that sulfonamide-resistant strains were present and that prophylaxis failed to reduce carrier rates, prophylaxis with sulfonamides was terminated in May, 1963. During the latter part of 1963, up to 90 percent of all strains isolated were resistant; thus far, in 1964, the proportion of resistant strains has generally been somewhat lower although varying widely from 10 to 80 percent. Approximately half of the cases have been caused by resistant organisms. Almost all sulfonamide-resistant strains have been Group B, although a few resistant Group C strains have been identified.

Since no effective chemoprophylactic agent was available, older but nonetheless useful procedures designed to reduce the degree of contact among recruits and to decrease their susceptibility to the disease assumed primary importance. Several such measures were put into effect during August and September. These included: (1) reduction of the recruit input at Fort Ord from 1100 men per week to 800 men per week; (2) institution of a platoon system to further restrict contact between men, not only to their own company, but to a single platoon: (3) cancellation of all leaves during the 8-week training period and prior to being transferred to their next duty station; (4) complete restriction of recruits to their company area; (5) the provision of additional barracks space to provide a minimum of 72 square feet of space per recruit; and (6) the provision of a minimum of a one-week free period for cadre personnel between recruit groups. The reduction in cases during September and October followed institution of these measures. The temporary discontinuation of recruit training, however, precludes a full evaluation of the effect of these measures.

Cases at Fort Ord have been satisfactorily treated with penicillin G in high doses (1,000,000 units or more

every 2 hours parenterally), with or without the addition of a sulfonamide drug. There has been no evidence to suggest that sulfonamide-resistant strains are any more or less virulent than the sensitive strains, nor has there been evidence suggesting that any of the deaths were due to antibiotic failure.

The occurrence of outbreaks of meningococcal meningitis due to Group B strains is in sharp contrast to previous experience. Group A strains have been responsible for most epidemics in the past, and Group C strains have been occasionally associated with outbreaks.

# Morbidity and Mortality Weekly Report

#### SUMMARY OF PNEUMONIA AND INFLUENZA DEATHS

The weekly average number of pneumonia-influenza deaths for the four-week period ending December 12 was 489 as compared with an expected weekly average of 522.

		Week	4 Week	Weekly		
	11/21	11/28	12/5	12/12	Total	Averoge
Observed	489	425	485	555	1,954	489
Expected	504	516	528	539	2,087	522
Excess	-15	-91	-43	16	-133	-33

(See table, page 443)

#### MENINGOCOCCAL MENINGITIS

(Continued from Page 439)

Substantial evidence, however, has accumulated that the Group B sulfonamide-resistant strains are at this time widely distributed throughout the civilian population. Ivler et al1 have shown that 25 percent of strains isolated from Los Angeles area civilian cases of meningococcal meningitis since mid-1963 were resistant to 10 mg percent of sulfadiazine. In Figure 4 are shown the results of sulfonamide sensitivity testing of 210 isolates from blood or cerebrospinal fluid submitted to the Communicable Disease Center. Sixty percent of these strains came from States other than California, and all but a few of the strains were Group B. Thirty-seven percent of the strains required 1.0 mg percent or more of sulfadiazine for inhibition; the sensitive strains were inhibited by 0.1 mg percent or less.

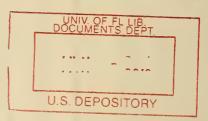

Resistance of meningococci to sulfonamides has not been accompanied by changes in resistance to penicillin or other antibiotics. It is important to emphasize that the presence of sulfonamide resistance in no way precludes successful treatment of clinical cases with penicillin G.

(Data submitted by Dr. Philip Condit, Chief, Bureau of Communicable Diseases, presented in "Epidemiological Notes" (October 30, 1964), California Department of Health; Colonel Adam Rapalski, Chief, Preventive Medicine Division, Department of the Army; and Laboratory Branch, CDC. Summary prepared in Investigations Section, Epidemiology Branch, CDC.)
